```

The validation risk, which initially was 1194.9857, decreases down to 1032.38697. We plot the validation risk over the number of iterations.

```

In [121]: xpos = np.arange(len(validation_risk_kernel_linear[0]))+ 1

plt.plot(xpos, validation_risk_kernel_linear[0], 'ro', ms =1)
plt.xlabel('Iterations')
plt.ylabel('the Validation risk')
plt.title('Stochastic gradient with the linear kernel')

plt.show()

```

**Does the quadratic kernel overfit the data?** According to the validation risk, the quadratic kernel does not appear to overfit the data. It gives lower validation risk than the linear kernel and the proportions of numbers of data and the total risk are almost the same in the validation risk and the training risk.

**For each kernel, should you decrease or increase  $\lambda$  to try to improve performance?**

We tried several different  $\lambda$  values in cross validation to see if they can improve performance. There was no noticeable decrease in the training risk compared to the training risk when  $\lambda$  is  $10^{-3}$ . This implies that there is no need to decrease or increase  $\lambda$  to improve performance.

**Kaggle** Based on training risks, or empirical risks, of each classifier, the best classifier is the logistic regression with batch gradient descent along with the third preprocessed data. We submitted the predicted labels to Kaggle that is derived by the best classifier, and the kaggle score was 0.78231.

```
In [35]: empirical_risk = logistic_with_batch_gradient(w_0, sp_xtrain3, sp_ytrain, 2e-3, 20000)
```

### 1.3.1 Problem 4: Revisiting Logistic Regression

Recall that in logistic regression, the logistic function,  $s(z) = \frac{1}{1+e^{-z}}$ , is used to map output values between  $[0, 1]$ . Consider the function  $g(z) = \frac{\tanh(z)+1}{2}$ , where  $\tanh(z) = 2s(2z) - 1$ , that also maps outputs between  $[0, 1]$ . In this problem, we will explore using  $g(z)$  instead of the logistic function in logistic regression.

$$g(z) = \frac{\tanh(z) + 1}{2} = \frac{2s(2z)}{2} = \frac{2}{2 + 2e^{-2z}} = \frac{1}{2} + \frac{1 - e^{-2z}}{2 + 2e^{-2z}} = \frac{1}{2} + \frac{e^z - e^{-z}}{2(e^z + e^{-z})}.$$

and

$$g'(z) = \frac{dg(z)}{dz} = \frac{2(e^z + e^{-z})(e^z + e^{-z}) - 2(e^z - e^{-z})^2}{4(e^z + e^{-z})^2} = \frac{1}{2} - \frac{\tanh(z)^2}{2}$$

The appropriate batch gradient ascent update function is

$$\begin{aligned} w &\leftarrow w - \lambda \nabla J(w) \\ &= w - \lambda \sum_{i=1}^n \left( \frac{y_i g'(X_i \cdot w)}{g(X_i \cdot w)} - \frac{(1 - y_i) g'(X_i \cdot w)}{1 - g(X_i \cdot w)} \right) X_i \\ &= w - \lambda \sum_{i=1}^n \left( \frac{y_i \left( \frac{1}{2} - \frac{\tanh^2(X_i \cdot w)}{2} \right)}{\frac{\tanh(X_i \cdot w) + 1}{2}} - \frac{(1 - y_i) \left( \frac{1}{2} - \frac{\tanh^2(X_i \cdot w)}{2} \right)}{1 - \frac{\tanh(X_i \cdot w) + 1}{2}} \right) X_i \\ &= w - \lambda \sum_{i=1}^n (2y_i - 1 - \tanh(X_i \cdot w)) X_i \end{aligned}$$

### 1.3.2 Problem 5: Real World Spam Classification

Linear SVM can not utilize the new feature as he desired, because the spams usually are sent around midnight and number of milliseconds since the previous midnight are concentrated in either  $(0, t]$  or  $[86400000 - t, 86400000)$  for small  $t$  and linear SVM can not classify whether this new feature is either in one of the two intervals  $(0, t]$  and  $[86400000 - t, 86400000)$  or not. Therefore in order to classify the feature correctly with linear SVM, Daniel may want to try one of following methods: 1. introduce the new feature as the number of milliseconds since the previous noon, rather than since the previous midnight so that the time around midnight could have continuous possible values, 2. use quadratic kernel instead of linear kernel so that the linear SVM can classify whether the new feature is either in one of the two intervals  $(0, t]$  and  $[86400000 - t, 86400000)$  or not.
