## 1 CS189: Introduction to Machine Learning

### 1.1 Problem 1: Ridge Regression

In this problem we will return to predicting the median home value in a given Census area by extending linear regression. The data is in `housing_data.mat` and it comes from <ftp://rcom.univie.ac.at/mirrors/lib.stat.cmu.edu/datasets/.index.html>. There are only 8 features for each data point; you can read about the features in `housing_data_source.txt`.

#### 1.1.1 1a)

In order to find the optimizer of the loss function  $J(w, \alpha)$ , we need to differentiate the loss function  $J(w, \alpha)$  and find the local minima. Before differentiating the loss function  $J(w, \alpha)$ , let us expand the mathematical expression to facilitate calculations.

$$\begin{aligned} J(w, \alpha) &= (Xw + \alpha \mathbf{1} - y)^\top (Xw + \alpha \mathbf{1} - y) + \lambda w^\top w \\ &= (w^\top X^\top + \alpha \mathbf{1}^\top - y^\top)(Xw + \alpha \mathbf{1} - y) + \lambda w^\top w \\ &= w^\top X^\top Xw + \alpha w^\top X^\top \mathbf{1} - w^\top X^\top y + \alpha \mathbf{1}^\top Xw + \alpha^2 n - \alpha \mathbf{1}^\top y + -y^\top Xw - y^\top \alpha \mathbf{1} + y^\top y + \lambda w^\top w \\ &= w^\top X^\top Xw - w^\top X^\top y + \alpha n - \alpha \mathbf{1}^\top y + -y^\top Xw - y^\top \alpha \mathbf{1} + y^\top y + \lambda w^\top w \quad (\because X^\top \mathbf{1} = \mathbf{1}^\top X = 0) \end{aligned}$$

If we differentiate the loss function  $J(w, \alpha)$  by  $w$ , then

$$\frac{\partial J}{\partial w} = 2X^\top Xw - 2X^\top y + 2\lambda w.$$

Therefore,

$$\frac{\partial J}{\partial w} = 2X^\top Xw - 2X^\top y + 2\lambda w = 0$$

gives  $\hat{w} = (X^\top X + \lambda I)^{-1} X^\top y$ .

If we differentiate the loss function  $J(w, \alpha)$  by  $\alpha$ , then we get

$$\frac{\partial J}{\partial \alpha} = 2n - 2\mathbf{1}^\top y.$$

In order for  $\frac{\partial J}{\partial \alpha}$  to be 0, it should be that  $\hat{\alpha} = \bar{y}$ .

#### 1.1.2 1b)

Average RSS on different tuned lambda valuse is given as follows:

Lambda	average RSS
1e-12	9425875042980.4492
1e-5	9425875042967.5977
1e-4	9425875042851.9395
1e-3	9425875041695.3809
1e-2	9425875030137.1055
1e-1	9425874915283.6348
1	9425873839646.3105
5	9425870659168.0137
7	9425870045690.5527
8	9425869982405.9648
9	9425870081144.416
10	9425870341696.4805
12	9425871347405.1973
20	9425881801097.7461
100	9426530937596.7383
1000	9480399010571.4824

It is when  $\lambda = 8$  that ridge regression with least squares achieves the lowest average RSS throughout 10-fold cross validation.

In [109]: *# RSS on validation data with the lambda 8 with the lowest cross-validation error.*

```
ridge = ridge_regression(center_housing_xtrain, housing_ytrain, 8)
w = ridge[0]
alpha = ridge[1]
one = np.linspace(1,1,len(housing_yvalid))
temp = (np.dot(center_housing_xvalid, w) + (alpha * np.transpose(one)) - housing_yvalid )
RSS = np.dot(np.transpose(temp), temp)
```

In [110]: RSS

Out[110]: 5782552884504.541

When we train ridge regression with lambda of 8, RSS on validation data is given as 5782552884504.541. Compared to 5794953797654.9834, RSS of linear regression in HW3, the ridge regression exhibits lower RSS and therefore fits better to the validation data than the linear regression does.

In [111]: w

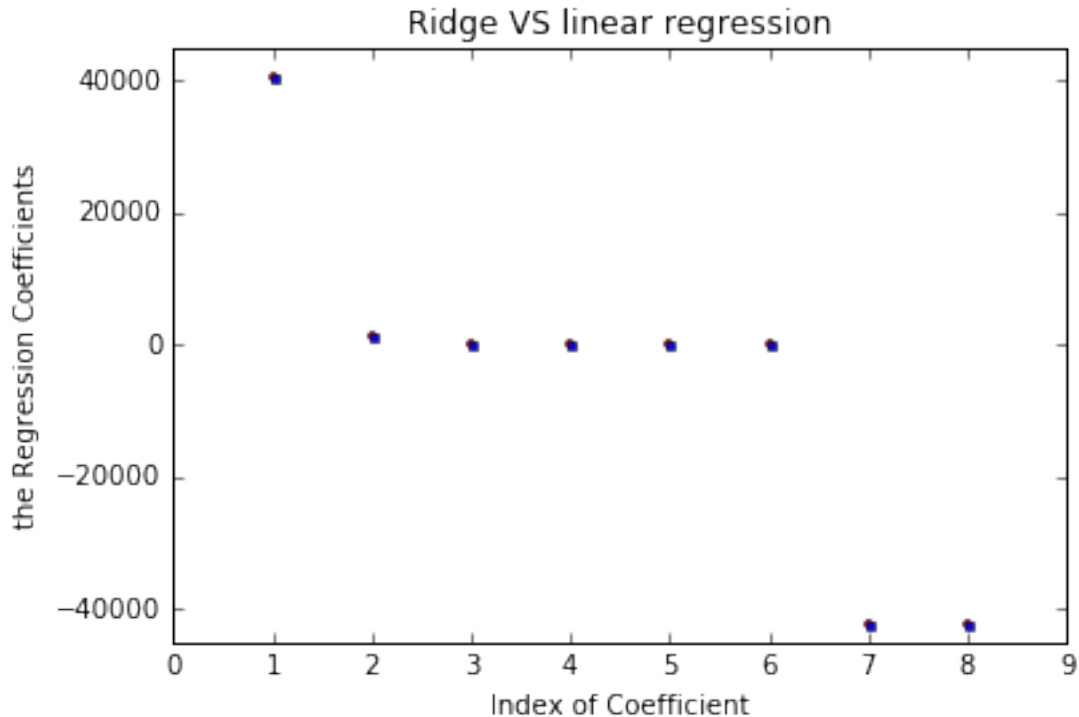

Out[111]: array([ 4.05915089e+04, 1.19668415e+03, -8.50719390e+00,

-4.21178034e+04, -4.23914057e+04])

In [115]: beta = np.array([ 4.05879986e+04, 1.19561189e+03, -8.50145688e+00,  
1.18352188e+02, -3.77900280e+01, 4.30562637e+01,  
-4.21794075e+04, -4.24573474e+04])

In [7]: import matplotlib.pyplot as plt  
%matplotlib inline

In [124]: xpos = np.arange(len(w))+ 1  
plt.axis([0,9, -45000, 45000])  
plt.plot(xpos, w, 'ro', ms = 3)

```
plt.plot(xpos, beta, 'bs', ms =3)
plt.xlabel('Index of Coefficient')
plt.ylabel('the Regression Coefficients')
plt.title('Ridge VS linear regression')
plt.show()
```

We plot the regression coefficients of 8 feature in both ridge regression and linear regression in HW3. This plot shows that the maximum absolute value of the regression coefficients is slightly smaller in the ridge regression than in the linear regression, as we could expected. Since we impose penalty on large norm of regression coefficient vector in ridge regression, the ridge regression tends to have smaller absolute value of regression coefficients.

## 1.2 Problem 2 : Logistic Regression

```
In [131]: X = np.array([[0,3,1],[1,3,1],[0,1,1],[1,1,1]])
          y = np.transpose(np.array([1,1,0,0]))
          1/(np.array([1,2,3]) + 1)
```

```

### 1.3 Problem 3: Spam classification using Logistic Regression

The spam dataset given as part of the homework in spam.mat consists of 5172 email messages, from which 32 features have been extracted. Please use the standard features for the first four parts of this problem. In part 5, we are asked to predict the labels of the test set in test.mat and submit the predictions to Kaggle. Feel free to use your own featurizes to boost up your score! One can imagine performing several kinds of preprocessing to this data matrix. Try each of the following separately:

1. Standardize each column to have mean 0 and unit variance.
2. Transform the features using  $X_{ij} \mapsto \log(X_{ij} + 0.1)$ , where the  $X_{ij}$  's are the entries of the design matrix.
3. Binarize the features using  $X_{ij} \mapsto I(X_{ij} > 0)$ .  $I$  denotes an indicator variable.

```
In [21]: # import the data
```

```

spam_data = sio.loadmat('./spam_dataset/spam_data.mat')
sp_test = spam_data['test_data']
sp_xtrain = spam_data['training_data']
sp_ytrain = spam_data['training_labels'][0,]
sp_test = np.hstack((sp_test, np.expand_dims(np.transpose(np.linspace(1,1, sp_test.shape[0])),

```

## Preprocessing

- Standardize each column to have mean 0 and unit variance.

In [22]: *# Standardize each column to have mean 0 and unit variance.*

```
col_mean = np.mean(sp_xtrain, axis=0)
col_std = np.std(sp_xtrain, axis = 0)
```

```
sp_xtrain1 = (sp_xtrain - np.expand_dims(col_mean,axis = 0))/np.expand_dims(col_std, axis = 0)
sp_xtrain1 = np.hstack((sp_xtrain1, np.expand_dims(np.transpose(np.linspace(1,1, sp_xtrain1.sh
```

- Transform the features using  $X_{ij} \mapsto \log(X_{ij} + 0.1)$ , where the  $X_{ij}$  's are the entries of the design matrix.

In [23]: `sp_xtrain2 = np.log(sp_xtrain + 0.1)`

```
sp_xtrain2 = np.hstack((sp_xtrain2, np.expand_dims(np.transpose(np.linspace(1,1, sp_xtrain2.sh
```

- Binarize the features using  $X_{ij} \mapsto I(X_{ij} > 0)$ .  $I$  denotes an indicator variable.

In [24]: `sp_xtrain3 = (sp_xtrain > 0) * 1`

```
sp_xtrain3 = np.hstack((sp_xtrain3, np.expand_dims(np.transpose(np.linspace(1,1, sp_xtrain3.sh
```

**Batch Gradient Descent** We run the batch gradient method with learning rate  $10^{-3}$  for the first preprocessing data.

In [25]: `w_0 = np.transpose(np.zeros(sp_xtrain1.shape[1]))`

In [26]: `def logistic_with_batch_gradient(w,X,y,e,n):`

```
    w_temp = w
    risk = []
    for i in np.arange(n):
        risk_temp = R(w_temp,X,y)
        print ('the risk is ', risk_temp, ': iteration ', (i+1))
        w_temp = batch_gradient(w_temp, X, y, e)
        risk = risk + [risk_temp]
    return [risk, w_temp]
```

In [27]: `empirical_risk1 = logistic_with_batch_gradient(w_0, sp_xtrain1, sp_ytrain, 1e-3, 2000)`

```

2000 iterations lower the training risk down to 2008.9034413. We plot the training risk (the empirical risk of the training set) vs. the number of iterations.

```

In [28]: xpos = np.arange(len(empirical_risk1[0]))+ 1
         plt.plot(xpos, empirical_risk1[0], 'ro', ms =0.4)
         plt.xlabel('Iterations')
         plt.ylabel('the Training risk')
         plt.title('Batch gradient with the First preprocessing method')
         plt.show()

```

We run the batch gradient method with learning rate  $10^5$  for the second preprocessing data.

```
In [29]: empirical_risk2 = logistic_with_batch_gradient(w_0, sp_xtrain2, sp_ytrain, 1e-5, 2000)
```

the risk is 1922.48406202 : iteration 1999
the risk is 1922.45047124 : iteration 2000

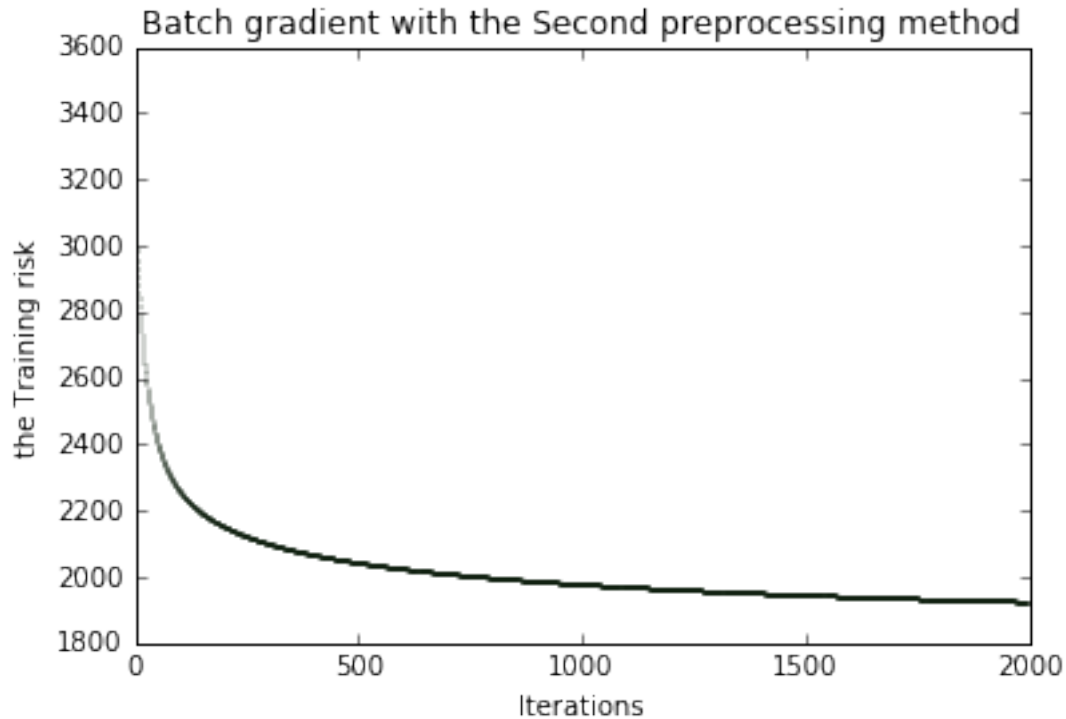

```

After 2000 iterations, the training risk decreases down to 1922.45047124, which is lower than what the first preprocessing method achieved. We plot the training risk over the number of iterations.

```

In [30]: xpos = np.arange(len(empirical_risk2[0]))+ 1
         plt.plot(xpos, empirical_risk2[0], 'go', ms = 0.4)
         plt.xlabel('Iterations')
         plt.ylabel('the Training risk')
         plt.title('Batch gradient with the Second preprocessing method')
         plt.show()

```

We run the batch gradient method with learning rate  $2 * 10^3$  for the third preprocessing data.

```
In [31]: empirical_risk3 = logistic_with_batch_gradient(w_0, sp_xtrain3, sp_ytrain, 2e-3, 2000)
```

the risk is 1820.96045369 : iteration 1999
the risk is 1820.95941468 : iteration 2000

```

After 2000 iterations, the training risk decreases down to 1820.95941468, which is the lowest among the three preprocessing method. We plot the training risk over the number of iterations.

```

In [32]: xpos = np.arange(len(empirical_risk3[0]))+ 1
         plt.plot(xpos, empirical_risk3[0], 'bo', ms =0.4)
         plt.xlabel('Iterations')
         plt.ylabel('the Training risk')
         plt.title('Batch gradient with the Third preprocessing method')
         plt.show()

```

### Stochastic Gradient Descent

In [3]: `import numpy.random as nr`

```
In [342]: def logistic_with_stochastic_gradient(w,X,y,e,n):
            w_temp = w
            risk = []
            nr.seed(0)
            indice = nr.choice(X.shape[0], n, replace =True)
            for i in np.arange(n):
                risk_temp = R(w_temp,X,y)
                j = indice[i]
                print ('the risk is ', risk_temp ,': iteration ', (i+1))
                w_temp = w_temp + e* (y[j]- s(np.dot(X[j,], w_temp)))* X[j,]
                risk = risk + [risk_temp]
            return risk
```

We run the stochastic gradient descent with learning rate  $10^{-2}$  on the first preprocessed data.

In [349]: `training_risk1 = logistic_with_stochastic_gradient(w_0,sp_xtrain1,sp_ytrain,1e-2,3000)`

```

```
In [380]: np.amin(training_risk1)
```

```
Out[380]: 2201.0702252575302
```

The training risk decreases down to 2206.8646236 after 3000 iterations and the smallest risk we obtained is 2201.0702252575302. We plot the training risk over the number of iterations.

```

In [379]: xpos = np.arange(len(training_risk1))+ 1
          plt.plot(xpos, training_risk1, 'ro', ms =1)
          plt.xlabel('Iterations')
          plt.ylabel('the Training risk')
          plt.title('Stochastic gradient with the First preprocessing method')
          plt.show()

```

We run stochastic gradient descent on the second preprocessed data with learning rate  $6 * 10^{-3}$ .

```
In [374]: training_risk2 = logistic_with_stochastic_gradient(w_0,sp_xtrain2,sp_ytrain,6e-3,3000)
```

```

```
In [376]: np.amin(training_risk2)
```

```
Out[376]: 2080.0943692828496
```

After 3000 iteration, the minimum of the training risk we obtained is 2080.0943692828496. We plot the training risk over the number of iterations.

```

In [378]: xpos = np.arange(len(training_risk2))+ 1
plt.plot(xpos, training_risk2, 'go', ms =0.7)
plt.xlabel('Iterations')
plt.ylabel('the Training risk')
plt.title('Stochastic gradient with the Second preprocessing method')
plt.show()

```

We run the stochastic gradient descent with learning rate 0.25 on the third processed data.

```
In [390]: training_risk3 = logistic_with_stochastic_gradient(w_0,sp_xtrain3,sp_ytrain,0.25,3000)
```

```

```
In [391]: np.amin(training_risk3)
```

```
Out[391]: 1928.7904915537711
```

After 3000 iterations, the training risk decreases down to 2065.03700687 and the smallest risk we obtained is 1928.7904915537711. We plot the training risk over the number of iterations.

```

In [392]: xpos = np.arange(len(training_risk3))+ 1
          plt.plot(xpos, training_risk3, 'bo', ms =0.7)
          plt.xlabel('Iterations')
          plt.ylabel('the Training risk')
          plt.title('Stochastic gradient with the Third preprocessing method')
          plt.show()

```

**Stochastic gradient descent VS Batch gradient descent** It appears that the convergence rate, the speed in which a method converge to the minima, is higher in the batch gradient descent and the batch gradient method guarantees continuous decrease in the training risk. However, the stochastic gradient descent takes shorter time to compute for each step.

**Stochastic gradient descent with learning rate decreasing over iterations**

```
In [407]: def logistic_with_stochastic_gradient_decreasing_stepsize(w,X,y,e,n):
            w_temp = w
            risk = []
            nr.seed(0)
            indice = nr.choice(X.shape[0], n, replace =True)
            for i in np.arange(n):
                risk_temp = R(w_temp,X,y)
                j = indice[i]
                print ('the risk is ', risk_temp, ': iteration ', (i+1))
                w_temp = w_temp + (e/(i+1)) * (y[j]- s(np.dot(X[j,], w_temp)))* X[j,]
                risk = risk + [risk_temp]
            return risk
```

We run the stochastic gradient descent with learning rate  $\frac{1}{t}$  at step  $t$  on the first preprocessed data.

```
In [434]: training_risk_1 =logistic_with_stochastic_gradient_decreasing_stepsize(w_0,sp_xtrain1,sp_ytra

the risk is 2518.08163549 : iteration 3000

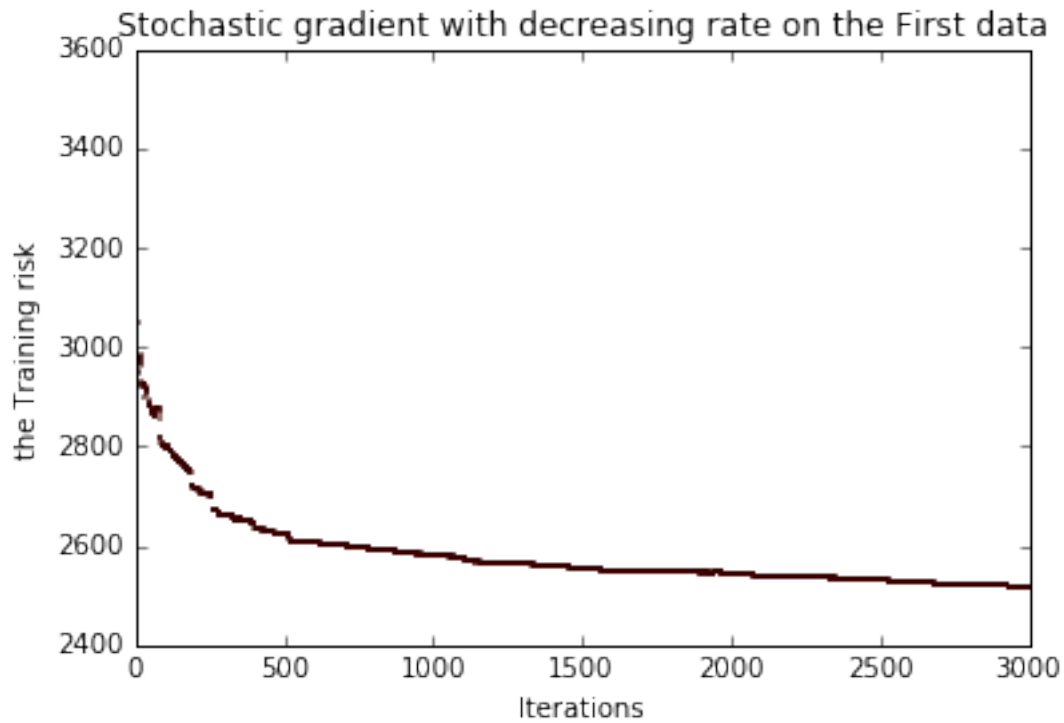

```

After 3000 iterations, the training risk decreases down to 2518.08163549. We plot the training risk over the number of iterations.

```

In [435]: xpos = np.arange(len(training_risk_1))+ 1
          plt.plot(xpos, training_risk_1, 'ro', ms =1)
          plt.xlabel('Iterations')
          plt.ylabel('the Training risk')
          plt.title('Stochastic gradient with decreasing rate on the First data')
          plt.show()

```

We run the stochastic gradient descent with the decreasing step size  $\frac{1.1}{t}$  at step  $t$ .

In [455]: `training_risk_2 =logistic_with_stochastic_gradient_decreasing_stepsize(w_0,sp_xtrain2,sp_ytra`

```

```
In [457]: np.amin(training_risk_2)
```

```
Out[457]: 2404.8189851332536
```

After 3000 iterations, the training risk decreases down to 2411.97082038 and the smallest risk we obtained is 2404.8189851332536. We plot the training risk over the number of iterations.

```

In [460]: xpos = np.arange(len(training_risk_2))+ 1

plt.plot(xpos, training_risk_2, 'ro', ms =1)
plt.xlabel('Iterations')
plt.ylabel('the Training risk')
plt.title('Stochastic gradient with decreasing rate on the Second data')
x1,x2,y1,y2 = plt.axis()
plt.axis((x1,x2,2400,3600))
plt.show()

```

We run the stochastic gradient descent with decreasing learning rate  $\frac{8}{t}$  at step  $t$  on the third preprocessed data.

```
In [473]: training_risk_3 =logistic_with_stochastic_gradient_decreasing_stepsize(w_0,sp_xtrain3,sp_ytra
```

```

After 3000 iterations, the training risk decreases down to 2301. We plot the training risk over the number of iterations.

```

In [474]: xpos = np.arange(len(training_risk_3))+ 1

plt.plot(xpos, training_risk_3, 'bo', ms =1)
plt.xlabel('Iterations')
plt.ylabel('the Training risk')
plt.title('Stochastic gradient with decreasing rate on the Third data')
x1,x2,y1,y2 = plt.axis()
plt.axis((x1,x2,2300,3600))
plt.show()

```

**Is this strategy better than having a constant  $\epsilon$ ?** With the constant step size (learning rate), the stochastic gradient produces lower training risk after the same number of iterations. This could be predictable in that the step size gets too small too fast when we use decreasing learning rates and therefore could not approach to the minimum as much as the stochastic gradient descent with constant step size does. It is worth to mention that the graph of training risk is much smoother curve with decreasing learning rate than with constant learning rate.

**kernel logistic regression with a polynomial kernel of degree 2**
